## $\overline{\underline{T H E}} \mathbf{N C S}{ }^{\text {m }}$

The National Community Survey ${ }^{\text {TM }}$

## Los Alamos County, NM <br> Comparisons by Demographic Subgroups 2020

## About the Demographic Comparisons

The National Community Survey ${ }^{\text {TM }}$ (The $\mathrm{NCS}^{\text {TM }}$ ) is a collaborative effort between National Research Center, Inc. (NRC) and the International City/County Management Association (ICMA). The survey and its administration are standardized to assure high quality research methods and directly comparable results across The NCS communities. Communities conducting The NCS can choose from a number of optional services to customize the reporting of survey results. Los Alamos County's Comparisons by Demographic Subgroups is part of a larger project for the County and additional reports are available under separate cover. This report discusses differences in opinion of survey respondents by length of residency, housing tenure, race and ethnicity, age, and gender.

## Understanding the Tables

For most of the questions, one number appears for each question. Responses have been summarized to show only the proportion of respondents giving a certain answer; for example, the percent of respondents who rated the quality of life as "excellent" or "good," or the percent of respondents who participated in an activity at least once. It should be noted that when a table that does include all responses (not a single number) for a question that only permitted a single response does not total to exactly $100 \%$, it is due to the common practice of percentages being rounded to the nearest whole number.

The subgroup comparison tables contain the crosstabulations of survey questions by selected respondent characteristics. Chi-square or ANOVA tests of significance were applied to these breakdowns of survey questions. A "p-value" of 0.05 or less indicates that there is less than a $5 \%$ probability that differences observed between groups are due to chance; or in other words, a greater than $95 \%$ probability that the differences observed in the selected categories of the sample represent "real" differences among those populations. As subgroups vary in size and each group (and each comparison to another group) has a unique margin of error, statistical testing is used to determine whether differences between subgroups are statistically significant.

Each column in the following tables is labeled with a letter for each subgroup being compared. The "Overall" column, which shows the ratings for all respondents, also has a column designation of "(A)", but no statistical tests were done for the overall rating.

For each pair of subgroups ratings within a row (a single question item) that has a statistically significant difference, an uppercase letter denoting significance is shown in the cell with the larger column proportion. The letter denotes the subgroup with the smaller column proportion from which it is statistically different. Subgroups that have no uppercase letter denotation in their column and that are also not referred to in any other column were not statistically different.

For example, in Table 1 on the following page, respondents age 55 and over (C) gave significantly higher rating to the overall quality of life than those age 35 to 54 (B), as denoted by the " $B$ " listed in the cell of the ratings for those $55+$. This was also true of people who were white alone, not Hispanic (A) over those who were Hispanic and/or other race (B) and homeowners (B) over renters (A).

TABLE 1: QUALITY OF LIFE

| PPercent rating positively (e.g., <br> excellent/good, very/somewhat <br> likely) |
| :--- |

TABLE 2: GOVERNANCE

| Percent rating positively (e.g., excellent/good) | Age |  |  | Sex |  | Race/ethnicity |  | Housing tenure |  | Length of residency |  |  | Overall <br> (A) |
